<b>1</b>	<b>client</b>	<b>1</b>
1.1	client module . . . . .	1
<b>2</b>	<b>Indices and tables</b>	<b>5</b>
	<b>Python Module Index</b>	<b>7</b>
	<b>Index</b>	<b>9</b>

## 1.1 client module

`client.Send_group_key (recipient, g_id)`

Sending the group key to someone. Used when we need to add someone or kick a person.

`client.add ()`

Used for adding a member to the group.

`client.add_friend ()`

When we want to make someone our friend. We can send messages to friends only.

`client.connect_balancer (balancerIP, balancerPort)`

This function is used to connect the client to the load balancer

**Parameters**

- **balancerIP** (*str*) – IP of balancer
- **balancerPort** (*int*) – Port of balancer

**Returns** socket of balancer

**Return type** socket

`client.connect_server (server_json)`

For connecting to a single server

**Parameters** **server\_json** (*list*) – contains information about the server

`client.connect_servers ()`

Used to connect client with all the servers

`client.create_group ()`

Creates a group with us as the only member. We can keep adding more people.

`client.execute_command (Command_type)`

The main execute function which is used when the user wants us to do something.

**Parameters** **Command\_type** (*str*) – The command the user want to perform.

**Returns** True for valid command else False

**Return type** bool

`client.get_name_locally (ID)`

Gets the name of a person who is already our friend

**Parameters** **ID** (*int*) – The ID of the person whose name we want

**Returns** Returns the name of the person if he is our friend else returns empty string

**Return type** str

`client.get_server(balancer)`

Asks the balancer for the server it should connect to

**Parameters** `balancer` (*socket*) – balancer socket

**Returns** Returns the server ID

**Return type** int

`client.group_image()`

For sending an image in a group. It is encrypted using a symmetric key which is only with the members of the group.

`client.group_message()`

For messaging in a group. It is encrypted using a symmetric key which is only with the members of the group.

`client.handle_New_group(message)`

This is used for getting the group\_ID of the group the client created from the server

**Parameters** `message` (*dict*) – The message the server sent in dict format with all fields

`client.handle_accept_friend(message)`

Handles when someone sends a friend request. It generates a symmetric key and sends the friend back using RSA

**Parameters** `message` (*dict*) – The message the person sent in dict format with all fields

`client.handle_add(message)`

The case when someone is added to the group.

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields.

`client.handle_friend_key(message)`

Handles the case when a friend send us a key for communication

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.handle_group_image(message)`

When we receive an image in a group. It is stored in our system as received\_(image title) format

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.handle_group_key(message)`

When we are new to a group the admin send us the key through RSA. This function stores that key in our local database.

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.handle_group_message(message)`

When we receive a message in a group

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.handle_kick(message)`

When someone is kicked from a group. It can be us or someone else. It is also ensured that new key will be generated for the group.

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields.

`client.handle_server(server)`

The main handle function when we receive something from the server. Different actions are taken depending on the type of message received.

**Parameters** `server` (*socket*) – the server socket

`client.handle_single_image(message)`

Handles the case when a friend sends us an image. It is stored in our system as received\_(image title)

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.handle_single_message(message)`

Handles the case when a friend sends us a message

**Parameters** `message` (*dict*) – The message the person/server sent in dict format with all fields

`client.help()`

Prints the basic commands for the help of the user

`client.kick()`

For kicking someone from a group. It is also ensured that we generate a new key and share to all members except the removed one through RSA for each member. Also only admin can kick from a group.

`client.q()`

Used for exiting the user

`client.register(server_json, pub_str)`

This is called when the client joins for the first time. For storing his credentials

**Parameters**

- **server\_json** (*list*) – Contains the information of the server
- **pub\_str** (*str*) – The public key of the client in str format

**Returns** ID assigned to the client by the server

**Return type** int

`client.request_pending_msgs()`

Used for requesting pending messages from the server

`client.single_image()`

When we want to send an image to a friend

`client.single_message()`

When we want to send a text message to a friend.

`client.write(balancer_sock)`

Gets a server from the balancer and takes a command from the user and executes the command through the server the balancer gave.

**Parameters** **balancer\_sock** (*socket*) – The socket of the balancer

## INDICES AND TABLES

- `genindex`
- `modindex`
- `search`
